

Round 2 — Speaking Scripts

Team Three Hacks | Startup Innovation Competition 2026 — Second Round

Deck: docs/PRESENTATION_ROUND2.pptx — **15 slides, 3 parts, one per speaker**

Backing document: docs/BUSINESS_PLAN.md / .pdf (hand this over afterwards)

How Round 2 is different from Round 1

In Round 1 the panel asked *"does it work?"* — and they answered that themselves.

They said the idea was good and they liked the build. Then they ran out of time and gave us homework.

So **do not pitch the detection again**. If we spend five minutes on helmets and number plates, we are answering a question nobody asked, in front of the same people who already said yes to it.

Round 2 is one question: ****how does this get onto a real road, and how does it make money?****

If a judge asks for a demo, say: **"Happily — it is running and we can show it in thirty seconds at the end. But you asked us seven business questions, so let us answer those first."**

The three parts

Part	Main focus	Speaker	Name	Slides	Time
—	Opening	Speaker 1 (me)	_____	1–2	1.5 min
1	Business — who will buy it, how we reach the police	Speaker 1 (me)	_____	3–5	4 min
2 ■	Technology — camera, AI, data, maps, detection flow	Speaker 2	_____	6–10	6 min
3	Money and rollout — pricing, revenue, launch, risk	Speaker 3	_____	11–15	5.5 min

About 17 minutes of speaking. Leave the rest for questions — this panel asks

a lot of them, and the questions are where we win.

Part 2 is the biggest on purpose. ■ The zone-data question is the one the panel pressed hardest on.

Speaker 1 says the final two sentences on slide 15, after Speaker 3 finishes that slide. The person who opened should close.

If we are given less time: cut slide 14 (SWOT) and hand it over as a document. Then cut slide 5. **Never cut slides 9 and 10.**

Slide map — one line per slide

#	Slide	Its one job
1	Title	Set the frame: this round is about deployment, not detection
2	You asked us seven questions	Show we listened. Buys goodwill in ten seconds
3	Who benefits is not who signs	Prove we know the customer, not just the user
4	The ladder to the Police	Decisive. The direct answer to "how do you reach the police"
5	The AI proposes, an officer decides	Decisive. Solves legal, trust and political risk at once
6	The whole system in six steps	Give them the map before the detail
7	Cameras already on the poles	CCTV import + the 400× bandwidth argument
8	What the AI does with one frame	Why the output can be trusted as evidence
9	Where the zone data comes from	Decisive. Reframes the hardest question so it can be answered
10	The world data already exists	The data is in government hands, and half the rules need none
11	How you subscribe or licence it	The price list, and the rules behind it
12	Is this the right price for Sri Lanka?	Decisive. Local credibility, including the late-payment risk
13	Western Province, three years	The revenue model, with the working shown
14	SWOT	Directly requested. Keep it honest or it is worthless
15	Launch, risks, and what we need	Implementation, challenges, the ask, and the close

OPENING — Speaker 1 — slides 1 and 2

Slide 1 — Title

[Do not start with the product. Start with what they told us.]

Good morning, and thank you for having us back. We are Team Three Hacks.

[Pause]

Last time you told us something we have not stopped thinking about. You said the idea is good, and the model runs well. And then you asked us how we would actually put it on a Sri Lankan road.

[Pause]

That is a harder question than building it. So we spent this round on that question, and only on that question.

Slide 2 — You asked us seven questions

You gave us seven things. Who is the customer. How we reach the police. How we import from existing CCTV. Where the zone data comes from at scale. The revenue model. A SWOT. And how we implement it in the real world.

This is our contents page. Each one is answered, and the slide number is next to it.

[Point at the three boxes at the bottom]

We have split this into three parts. **Part one is the business — who will buy it. Part two is the technology — the camera, the AI, the data and the maps. Part three is the money and the rollout.**

[Look up]

We have not pitched the detection again. You already told us it works.

PART 1 — Business — Speaker 1 — slides 3 to 5

Slide 3 — Who benefits is not who signs

The first thing we got wrong last time was this. We kept saying "our customer is the police". That is who *benefits*. It is not who *signs*.

[Point at the last column]

A private fleet can sign in two weeks. A municipal council takes one to three months. The Sri Lanka Police takes twelve to twenty-four months, because a national police contract needs supplier registration, audited accounts and a performance bond.

[Slow down]

So the police are our biggest customer and our slowest customer. Three students cannot live for two years with no revenue.

[Point at the box at the bottom]

That is why we run two tracks at the same time. Fleets, campuses and ports are private roads. No procurement. No legal complexity. The owner signs in a week.

****That private money is what pays for the two years it takes to reach the police.****

Slide 4 — The ladder

This is our answer to "how do you connect with the Sri Lanka Police". We do not walk into headquarters and ask for a contract. We climb a ladder.

Rung one. We give away evidence, not enforcement. A free thirty-day road safety audit at one junction, for one council. We issue zero fines. At the end we hand them a report: at this junction, in thirty days, this many riders with no helmet, this many going the wrong way, and these are the peak hours. Nobody gets fined, so nobody gets angry. It costs us two cameras and a month of electricity.

Rung two. We get a named champion. We take that report to the National Council for Road Safety and to Police Traffic Headquarters. We ask for one thing, and it is free for them to give — a letter of support. That letter is the most valuable thing in this whole plan.

Rung three. A supervised pilot in one division, and we publish the results honestly, including the bad ones.

Rung four. Procurement — through the side door. We sub-contract under an integrator who already holds government vendor registration. That turns a two-year procurement problem into a two-month partnership.

[Point at the bottom box]

Notice that every rung is something the other side can say yes to without spending money or taking a risk.

Slide 5 — The AI proposes, an officer decides

[This is a slow slide. Let it sit.]

There is one design decision that makes all of this possible, and I want to say it clearly.

[Pause]

The AI proposes. A police officer decides.

Every violation goes into an officer's review queue, with the photograph, the rule it broke, and how confident we are. It becomes a real fine only when a human presses approve.

[Pause]

That one choice solves four problems at once. **Legally**, a human is accountable, not an algorithm. **For trust**, no citizen is ever fined by a machine. **For accuracy**, every time an officer rejects one, that is us measuring our own error rate for free. And **politically**, it kills the headline "a robot fined me" before anyone can write it.

We are not asking a court, or a country, to trust an algorithm.

[Hand over] — *Now [Speaker 2] will show you how it actually works, and answer the question you pressed us hardest on.*

PART 2 ■ — Technology — Speaker 2 — slides 6 to 10

This part answers three of the seven questions. Take your time here. If anything runs over, it should be Part 3, not this.

Slide 6 — The whole system in six steps

Thank you. Before the detail, here is the whole thing on one slide. Six steps.

One, the camera. It can be a council's existing CCTV, our own camera, or a drone — we fly one today. We read the video with a standard called ONVIF.

Two, the edge box. One small computer, in the cabinet that is already on the pole. It handles about four cameras.

Three, detect. The AI finds vehicles, riders, helmets, phones and number plates, and gives each vehicle an identity number that stays with it as it moves.

Four, measure. This is where the map comes in. The calibration turns pixels into metres, so we get a real speed and a real position on the road — not a guess.

Five, judge. Ten rules run at the same time. Each one needs several frames to agree before it will accuse anybody.

Six, evidence. A photograph, with the plate, time, place and rule stamped on it, goes into an officer's queue. When the officer approves it, it becomes a challan.

[Point at the bottom line — this is the sentence that matters]

Only step six ever leaves the site. Everything before it happens on the pole.

Slide 7 — Cameras already on the poles

You asked how we get data out of the CCTV that already exists.

Almost every camera and recorder installed in this country speaks a standard called ONVIF, over RTSP. We just pull the stream. No firmware change, no rewiring, nothing new on the pole. If a council has two hundred cameras, we can be reading them the same week.

We use three sources — council CCTV that is already paid for, our own camera where none exists, and a drone.

[Point at the table]

Now, this is the important part. If you send a thousand video streams to a central server, that is two gigabits per second, continuously, and about twenty-one terabytes a day. That will not work on a municipal network in Sri Lanka.

So we do the detection at the edge, on that small box, and we send only the *events*. A complete violation record with its photograph is about two hundred and fifty kilobytes.

[Pause]

That is roughly four hundred times less bandwidth. That is the difference between this being deployable on the infrastructure Sri Lanka already has, and not being deployable at all.

[Point at the bottom box — say it, do not skip it]

And one honest warning. Most municipal CCTV here was installed to watch for theft, not to read number plates. It is mounted high and angled wide. We expect only about forty percent of any existing estate to be usable for enforcement without repositioning. We survey it and tell the customer that number **before** they sign, not after.

Slide 8 — What the AI does with one frame

Now, what happens inside. Six steps — and I want you to notice something about them.

Detect. One pass of the model finds vehicles, people, helmets, phones and plates.

Track. The same motorcycle keeps identity number forty-seven across frames. That lets a rule watch a vehicle over time, instead of judging one photograph.

Associate. Is this person actually *on* that motorcycle? We check the overlap, the centre position, and where the feet are. That is what stops a pedestrian standing next to a bike being fined for no helmet.

Persist. Three or four frames must agree before we accuse anybody. One bad frame is never enough.

Measure. Is the vehicle really moving? We measure how far it actually travelled, with the camera's own shake removed. So a parked bike can never be fined.

Refuse. And if the camera is not calibrated, the rules that need geometry do not run at all. We had a speed estimate that said one hundred and fifty five kilometres an hour for a car sitting still at a junction. We deleted it, rather than ship it.

[Look up — this is the point of the slide]

Four of those six steps exist to *stop* the system firing, not to make it fire. In a product whose output is evidence, that is the whole job.

Slide 9 — Where the zone data comes from

Now the question you pressed us hardest on. When you go from one junction to a whole city, where does the zone data come from? The speed limits, the parking areas, the road limits.

That was the best question we got, and honestly, we did not have a good answer on the day.

[Pause — this admission is worth more than a slick answer]

Here is what our demo hides. Today a human opens a clip, clicks four corners of the road, and types in the real distance. Fine for five cameras. Impossible for five thousand.

But when we pulled it apart, we found we had been mixing up two completely different kinds of data.

[Point at the table]

The top row is **camera geometry** — where the ground actually is in *this* picture. That really does have to be done once per camera. Every camera sees a different scene. There is no way around it.

The bottom row is **world knowledge** — what the law says about this piece of road. The speed limit. Whether parking is allowed. Which way traffic goes.

[Slow]

That does *not* belong to the camera. It belongs to the map.

So we fixed the geometry part. Instead of clicking corners and typing metres, the operator drags four points on the camera image and the matching four on a satellite map. That one act gives us metres per pixel for speed, the stop line, the legal direction of travel, and the no-parking areas — all at once.

[Point at the four numbers]

Four minutes a camera. A thousand cameras is sixty-seven person-hours. Two people, two weeks, for a whole province. And if somebody knocks the camera, we detect it and stop enforcing until it is recalibrated.

That is a line item on a budget. It is not a blocker.

Slide 10 — The world data already exists

And the world knowledge — the limits and the no-parking zones — we do not create it. It already exists, and mostly it is already in government hands.

[Left box]

The Road Development Authority holds the road register. The Survey Department holds the built-up-area boundaries, and that is what legally decides whether a road is fifty kilometres an hour. The municipal councils hold the gazetted traffic schemes — no parking, one way, bus halts. They are paper and PDF today; digitising Colombo's is a few weeks of work for one person, once. OpenStreetMap is free and already has speed limits and one-way flags for urban Sri Lanka.

[This is the good line — slow down]

And where we know nothing at all, we use the default limit in the Motor Traffic Act for that class of road. No sign, no survey, no data entry. **The law itself is the data.**

[Right box]

And here is the part we are proudest of, because it was already built before you asked.

Six of our ten rules need **no map at all**. No helmet. Triple riding. Stunt riding. Phone use. Rest breaks. They work on day one, anywhere.

The other four wait. And they do not wait by guessing — they wait by switching off.

[Look up]

So the honest answer is: the data problem is real, it is a few weeks of work per province, and it does not stop us deploying on day one. The customer sees value in week one, not month six.

[Hand over] — *Now [Speaker 3] will take the money.*

PART 3 — Money and rollout — Speaker 3 — slides 11 to 15

Slide 11 — How you subscribe or licence it

Thank you. You asked how somebody actually subscribes or licences this. Here it is.

The top row is free, and that is deliberate — it is the thirty-day audit [Speaker 1] described. It is how we get in the door.

Then it is per camera, per month. Three thousand five hundred rupees for the core rules. Five thousand five hundred with plate recognition and printed challans.

[Point at the no-upfront row]

This row matters more than it looks. Same service, but the setup and the hardware are rolled into the monthly fee over three years, so the customer pays nothing up front.

Fleets pay per vehicle — a thousand rupees a vehicle per month — because that is the unit a fleet owner counts in.

[Point at the Provincial Licence row]

And this is the big one. A ministry does not want a per-camera cloud subscription. They want unlimited cameras, **on their own premises**, with a service agreement. Twelve million rupees per province per year. A police force will not put criminal evidence in somebody else's cloud — and honestly, they should not. So on-premise is not a compromise for us. It is our highest margin product.

[Point at the three boxes at the bottom]

Three rules produced those numbers.

One. We anchor on the alternative, not on our cost. If we priced on cost we would charge about twelve hundred rupees. But the buyer's real alternative is three constables at three hundred thousand rupees a month.

****Two, and this is the most important rule for selling to government. Operating cost, not capital cost.**** A council officer can approve a monthly maintenance line inside a budget they already have. A *purchase* needs a capital vote and a tender, and that adds six to eighteen months. That is why the no-upfront option exists.

Three. We publish the volume tiers before anyone asks — three thousand at a hundred cameras, two thousand two hundred above two thousand. Otherwise we are negotiating a discount from zero, in the room, under pressure.

Slide 12 — Is this the right price for Sri Lanka?

But a price is only right if the person signing can actually approve it. So we tested every tier against the budget it would come out of.

A council with forty cameras pays one point six eight million rupees a year. That is less than two constables cost for a year, and it fits a maintenance line they already have.

Police Headquarters, for a whole province, pays twelve million a year. Against the national police budget that is a rounding error. No new budget vote is needed.

A fleet of twenty five vehicles pays a thousand rupees per vehicle per month. That is about ten percent of a commercial motor insurance premium. So a ten percent discount makes it free.

And against imported software — an imported ANPR licence runs two hundred to a thousand US dollars per camera per year. We are about a hundred and forty. Three to seven times cheaper.

[Point at the big line]

Overall, roughly fifty times cheaper per hour of coverage than three constables, at about seventy four percent gross margin.

[Now the honest box — do not rush this]

But I want to name the real risk, and it is not the price.

[Pause]

Government in Sri Lanka pays in ninety to a hundred and eighty days. That delay — not the price — is what kills small vendors selling to the public sector.

So we plan for it. Twenty five percent of the activation fee is invoiced before field work starts. The provincial licence is billed quarterly **in advance**, not in arrears. And we hold private-sector revenue as working capital to bridge the gap.

We would rather price this so a council can say yes this quarter, than price it so it looks impressive on a slide.

Slide 13 — Western Province, three years

You asked us to fix a province and show the revenue. We chose Western Province — Colombo, Gampaha, Kalutara. Highest vehicle density, highest crash count, the most existing CCTV, and Police Headquarters and the National Council for Road Safety are both physically there.

Year one is small on purpose. Eighty cameras, about thirty six thousand dollars of revenue. We lose about ten million rupees, and that loss *is* our ask.

Year two, six hundred cameras, the provincial licence signs, and we cross into profit. That is our breakeven year.

Year three, three more provinces and a first export pilot — about a million dollars.

[Point at the footnote — say it out loud, do not let them find it]

And I want to be direct. These are our own modelled assumptions. We have shown you the working — the camera counts, the price, the headcount — so you can push on any line of it. But we are not presenting them as published facts.

[Point at the bottom box]

And I will say the thing you are already working out. Fully saturated, Sri Lanka is only about one point six million dollars a year. **Sri Lanka alone is not a big enough market to build a big company in.** But it is exactly the right market to *prove* one in — because the same product, unchanged, fits Bangladesh, Nepal, Vietnam and East Africa, where the traffic is the same mix of motorcycles and three-wheelers, and the death rate is worse.

Slide 14 — SWOT

You asked for a SWOT. Here is an honest one. I will stop on two lines.

[Point at Weaknesses]

The second one. **We do not have a measured accuracy number yet.** We have not tested against a labelled Sri Lankan ground-truth set, so we cannot tell you our precision — and a court will eventually ask. That is our number one engineering priority.

And the third one. Our seatbelt rule is switched off. The model we obtained turned out to be broken — it called a driver wearing a belt a violation, and it called an empty motorway a violation too. So we disabled the rule rather than ship something that accuses innocent drivers.

[Look up]

We would rather tell you that than have you find it.

[Point at Threats, briefly]

And the biggest threat is real. Hikvision, Dahua and Huawei can give this software away free to win the camera hardware contract. Our answer is not to compete on price. We run *on top of* their hardware and sell what they cannot — accuracy on Sri Lankan traffic, data protection compliance, data that stays in the country, and an engineer who turns up the same afternoon.

Slide 15 — Launch, risks, and what we need

Last slide. Three columns.

[Left] How we launch it. The first three months we incorporate, publish real accuracy numbers, and build the officer review queue. Then the free audit, then the letter, then a supervised pilot. Private customers run in parallel and keep us alive. Western Province and breakeven by month twenty-four.

One thing I want to flag: to deliver a fine you have to turn a number plate into a registered owner, and that needs a data-sharing agreement with the Department of Motor Traffic. That is the longest-lead item in the whole plan, so we start it in month four, not month twenty.

[Middle] What will go wrong. Six things, each with what we do about it. Let me take one — the one nobody talks about. Somebody will ring up and ask for a challan to disappear. So every view, every approval and every cancellation is written to a log that cannot be edited, with a named officer against it. We cannot stop it happening. We can make sure it leaves a mark.

[Right] What we need. Fifteen million rupees — about fifty thousand dollars — for eighteen months. Sixty percent is salaries.

[Slow down — this is the real ask]

But there are four things we need that are not money, and honestly they are worth more to us than the money. A letter of support from the National Council for Road Safety or Police Traffic Headquarters. One council willing to host a free thirty-day audit. An introduction to a government IT integrator who already has vendor registration. And access to a labelled Sri Lankan traffic dataset.

If anyone in this room can make one of those four introductions, that is worth more to us than the cheque.

[Speaker 3 stops here. Speaker 1 says the last two lines.]

Speaker 1 — the close

We already built the hard part. You told us that yourselves last time. What we are asking for now is the boring part — one council, one letter, one pilot.

Thank you. We are very happy to take your questions.

Expected questions

Handling rule: answer in one sentence, then stop. In Round 1 we lost time to long answers. If they want more, they will ask. And if the answer is "we do not know yet", say that — this panel rewarded honesty last time.

Who takes what: business and strategy → Speaker 1. Camera, AI, data, maps → Speaker 2. Anything with a number in it → Speaker 3. If you are not sure, say "[name] built that part" and hand over. That looks like a team, not a hesitation.

On money

They ask	We say
Where did LKR 3,500 come from?	We priced against the alternative. Covering one point around the clock takes three constables — about three hundred thousand a month. We are roughly fifty times cheaper per point-hour, at about seventy four percent margin.
Can a Sri Lankan council actually afford this?	Forty cameras is one point six eight million a year — less than two constables cost for a year. And we offer it with no upfront fee at all: five thousand a month with the setup rolled in over three years.
Why does "no upfront" matter so much?	Because a council can approve a recurring cost easily, but a purchase needs a capital vote and a tender, which adds six to eighteen months. We would rather earn the same money in a shape they can sign.
What if a ministry demands a lower price for 2,000 cameras?	We quote the published tier — two thousand two hundred — or the flat provincial licence. We published the ladder in advance precisely so we never negotiate down from one number under pressure.
Government pays late. How do you survive?	That is the real risk, not the price. Twenty five percent of activation up front, the licence billed quarterly in advance rather than in arrears, and private revenue held as working capital.
Why subscription and not a share of the fines?	Fines are public revenue, so a private share is an audit problem. Being paid per fine means wanting more fines, and our goal is fewer violations. And "startup profits from fining motorists" ends us in a week.
What does it cost you to serve one camera?	About nine hundred rupees a month in compute, storage and support. That is where the seventy four percent margin comes from.
Sri Lanka is too small a market.	Agreed, and we said it before you did — about one point six million dollars fully saturated. Sri Lanka is where we prove it. The same product fits Bangladesh, Nepal, Vietnam and East Africa.
What is your valuation?	We have not set one, and we would rather agree it with an investor who understands this sector than pick a number to sound confident. What we know is what we need: fifteen million rupees for eighteen months.
Is there a market outside enforcement?	Yes — anonymised analytics. Insurers pricing risk, the RDA finding blackspots, researchers. No plates, no faces, just where and when the danger is.

On the technology

They ask	We say
How do you get parking zones and speed limits for a whole city?	By separating two things our demo mixed up. Camera geometry is four minutes per camera — two people, two weeks, for a province. World knowledge belongs in the map and already exists in the RDA register, council gazettes and OpenStreetMap. Where nothing is known, the statutory default applies. And where we still do not know, the rule does not fire.
What if the camera gets moved?	We detect it — the background of the scene changes — and the system stops enforcing the geometry rules and asks to be recalibrated, rather than quietly fining the wrong people.
Can you handle a thousand cameras?	Not by sending a thousand video streams anywhere — that is two gigabits a second. We detect at the edge and send only events, about two hundred and fifty kilobytes each. Four hundred times less bandwidth.
What hardware does each site need?	One small computer in the existing cabinet, handling about four cameras, on a small battery. We run on the CPU today — no graphics cards, no data centre.
How do you connect to a council's cameras?	ONVIF over RTSP, which almost every installed camera already speaks. Nothing on their side changes.
What if their cameras are useless?	We expect about forty percent of any estate to be usable without repositioning. We survey first and put that number in writing before anyone signs. Where cameras will not do, we supply our own — which is revenue, not a problem.
How do you stop it fining the wrong person?	Four of the six steps inside the system exist to stop it firing. We check the person is really on the bike, we need several frames to agree, we check the vehicle is really moving, and we refuse the geometric rules on an uncalibrated camera. Then an officer still has to approve it.
Is your evidence admissible in court?	The Evidence Special Provisions Act of 1995 admits computer evidence if you can show the system was operating properly — so we keep a calibration certificate per camera, a log that cannot be edited, and an officer approves every fine. We are not asking a court to trust an algorithm.
What about privacy?	No face recognition, ever. Plates only, for a lawful purpose, ninety days then automatic deletion. That is designed against the Data Protection Act of 2022. Our analytics product has no plates and no faces at all.
What is your accuracy?	We do not have a defensible number yet and we are not going to invent one. Publishing real precision and recall per rule against a labelled Sri Lankan set is our first engineering priority. What we can show today is the opposite discipline — we switched off our speed estimate, our red light rule and our seatbelt rule because they were confidently wrong.
Does it work at night, or in rain?	Detection degrades, and plate reading degrades faster. We never issue a challan on a low-confidence plate — it goes to a human instead. Sites where plates matter get infrared-capable cameras.
What about power cuts?	The edge box runs on a small battery and queues events locally. When the link comes back, it syncs. Nothing is lost.

The awkward ones

They ask	We say
You are three students. Why you?	Because we built it, it runs, and we are here. We are not claiming we can negotiate a national procurement contract — that is exactly why our plan sub-contracts under a registered integrator instead of bidding alone.
Hikvision will give this away free.	That is our biggest commercial threat and we plan for it directly. We do not compete on price. We run on top of their hardware and sell what they cannot: accuracy on Sri Lankan traffic, data protection compliance, data that stays in the country, and an engineer who turns up the same afternoon.
What if the government says no?	Then we still have a fleet, insurance and campus business that does not need them — and in two years we have the accuracy record and the references that make the answer different.
What happens when you graduate?	We incorporate now with a vesting agreement, and the first thing the seed money buys is a full-time engineer. We are not pretending this survives on goodwill.
Isn't this just surveillance?	It is enforcement of laws that already exist, with an officer accountable for every decision, no face recognition, and a ninety-day deletion policy. The alternative is not privacy — the alternative is three thousand deaths a year and nobody watching.
Your seatbelt feature still doesn't work.	Correct, and it is on our SWOT. The model we obtained calls a belted driver a violation and calls an empty road a violation. We disabled the rule rather than accuse innocent people. Fixing it needs a detection model trained on our own data.
What have you changed since Round 1?	Nothing about the detection — you told us that worked. What changed is that we now know who signs, how we reach them, what it costs, what it earns, and what will go wrong. That is what you asked for.

Six rules for the call

1. **Do not pitch the detection again.** They already said yes to it.
2. **Answer in one sentence, then stop.** Silence is fine. They will ask for more.
3. **Say the weakness before they find it.** It worked last time. Do it again.
4. **Every number gets its working.** "Fifty times cheaper" is followed immediately by "three constables at a hundred thousand each".
5. **Never say a figure we cannot source.** Say "our assumption is" and mean it.
6. **The ask is four introductions, not a cheque.** Make sure that lands before we stop talking.

Team Three Hacks — Startup Innovation Competition 2026, second round.
